### **I** Abstract

This bachelor thesis is about writing a simple scripting environment for scientific computing, with focus on visualizations and interaction. Focus on visualization means, that every variable can be inspected and visualized at runtime, ranging from a textual representation to complex 3D scenes. Interaction is achieved by offering simple GUI elements for all parts of the program and the visualizations. All libraries are implemented in Julia and modern OpenGL, to offer high performance, opening the world to scientists who have to work with large datasets. Julia is a novel high-level programming language for scientific computing, promising to match C speed, making it the optimal match for this project. -This section needs more work, and should probably be written in the end

### 1 Introduction

This Bachelor Thesis is about writing a fast and interactive visualization environment suitable for scientific computing. As GUI elements and editable text fields are supplied, one can also write and execute scripts, and immediately visualize all bound variables of the script and edit them via simple GUI elements like sliders. The focus is on creating a modular library, that is written in a fast high-level language, making the library easy to extend. The introduction is structured in the following way. First, an introduction to the general field of research and its challenges is given. From these challenges, the problems relevant to this thesis will be extracted. Finally this chapter will conclude with a solution to the problem, how to measure the success and give an outlook on the structure of the entire Bachelor Thesis.

#### 1.1 Field of Research and Problem

Figure 1: different visualizations of  $f(x,y,z)=\sin(x/15)+\sin(y/15)+\sin(z/15)$ , visualized with Romeo. From left to right: Isosurface, isovalue=0.76, Isosurface, isovalue=0.37, maximum value projection

The very general research field is making computer science more accessible and understandable. This is especially relevant for users, who don't have a broad background computer science, or programmers implementing complicated state of the art algorithms. These users can be found especially in scientific computing, which makes this field the focus of this bachelor thesis. More precisely, it focuses on research which involves writing short scripts, while visualizing the results. An example would be a material researcher, who is investigating different shapes and materials and their reaction to pressure. The researcher would need to read in the 3D object he wants to analyze, have an easy way to tweak the material parameters and it would be preferable to get instant feedback on how the pressure waves propagate through the object.

Several demands by the researcher makes it challenging, to offer software for this area.

#### • Visualizations

Visualizations are a key element to understanding and access to complicated algorithms. In some domains, problems become only managable by visualizing them. One example is a function describing a 3D volume, like  $f(x,y,z)=\sin(x/15)+\sin(y/15)+\sin(z/15)$ . This is a simple function, which is already not that easy to interpret. Especially for more complex functions, visualizing might be the only way to get a deeper understanding of the function 1. Secondly, research is getting published, together with visualizations explaining the results. As they represent the research to the public, they should be as understandable as possible and preferably look good. Offering a creative, interactive work flow can make this challenge considerably easier.

#### • Money and Time is constrained

This means the research has to conclude quickly and most likely, it is not an option to employ a person or even a company to solve sub problems. From this we can deduce three preferences: If code needs to be written, it should be in an easy to understand high-level language. Computation times and feedback should be without delay to speed up development. The used libraries should be accessible to the researcher, because when something doesn't fit his demands, he most likely needs to resolve it himself due to the money constraint.

#### • Speed

Speed can be both seen as a usability or a time/money constraint. While the money/time constraint is obvious, even slightly slower software can reduces usability by a large degree. This is, because it hinders immidiate feedback. While scientists are used to slow computing times of their complicated algorithms, it still holds that it is far more satisfying and productive to immidiately see the results of your work. If the simulation of pressure takes 30 minutes compared to 1 second, this is not only frustrating, but has an immidiate influence on how many material combinations the researcher can try out in one day.

#### 1.2 Problem Solutions and Measurements of Success

\* Write it in one, open source, high level, high performance language (Julia) \* Write it in OpenGL \* Open Source \* Easy ways of creating GUIs \* Modularity \* Offer a broad variety of visualization

#### 1.2.1 Visualizations and Interaction

Having visualizations are the main purpose of the written software in this thesis.

#### 1.2.2 Extensibility

As previously deduced, extensibility is an important factor, which can decide, if a library is fit for scientific computing or not. It's not only that, but also a great factor determining growth of a software, as the more extensible the software is, the higher the probability that someone else contributes to it. In order to write extensible software, we first have to clarify what extensibility is. Extensible foremost needs, that the code is accessible. There are different levels of accessibility. The lowest level is closed source, where people purposely make the code inaccessible. While this is obvious, this is just a special case of not understanding the underlying language. Just shipping binaries without open sourcing the code, means that the source is only accessible in a language which is extremely hard to understand, namely the machine code of the binary. So other examples for inaccessibility are writing in a language that is difficult to understand. Other barriers are obfuscated language constructs, missing documentations and cryptic low level code. Further more the design of the library in the whole is an important factor for extensibility. It's not only important, that all parts are understandable, but also, that every independent unit in the code solves only one problem. If this is guaranteed, reusability in different contexts becomes much more simple. This allows for a broader user base, which in turn results in higher contributions and bug reports. Short concise code is also important, as it will take considerably less time to rewrite something, as the amount of code that has to be moved is shorter and less time is spend on understanding the code.

So the code written for this thesis should be open source, modular, written in a high level language and concise.

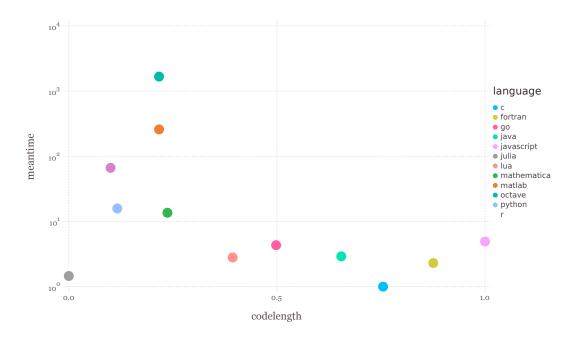

Figure 2: Languages speed relative to C (averaged benchmark results), plotted against the length of the needed code

#### 1.2.3 **Speed**

How to achieve state of the art speed with a high level language is an on going research and basically the holy grail of language design. Luckily, there is Julia building uppon Low Level Virtual Machine (LLVM), promosing a concise, high-level programming style, while approaching C-performance. This can be seen very well in figure 2. LLVM is a nice compiler infrastructure, which has frontents for different languages and different backends for different chip architectures. A language designer has the task, to emit LLVM Intermediate Representation (IR), which than gets just in time compiled and optimized to the architecture by LLVM. This concept is very nice, as you can accumulate state of the art optimizations in one place, making them accessible to many languages, while being able to compile to different platforms. There are x86, ARM, OpenCL and CUDA backends. While Julia doesn't support them all, it will hopefully be possible in the future. As LLVM is also used by Clang, the C/C++ frontend for LLVM rivaling gcc and Apple with Swift, LLVM is a very solid basis for a language. See table 1, for a little benchmark.

To get high performant 3D graphics rendering, there are on the first sight a lot of options. If you start to take the previously demands into account, the options shrink down. It should be implemented in one high level language, which can be used for scientific computing and has state of the art speed. At this point, there are close to zero libraries left. As you can see in figure 2, Matlab, Python and R disqualify, as they are too slow. Javascript,

Java, Go and Lua are missing a scientific background and the others are too low level for the described goals. This leaves only Julia, but in Julia there weren't any 3D libraries available, which means that one has to start from scratch. There are only a couple of GPU accelerated low-level libraries available, namely OpenGL, DirectX and Mantel. This leaves one library, if you additionally introduce the constraint of cross-platfrom compability. So for the purpose of high speed visualizations, OpenGL was wrapped with a high-level interface written in Julia. This leaves us with one binary dependency not written in Julia, namely the video driver, which implements OpenGL.

#### 1.3 Outlook

- 1.4 Used Technologies
- 1.4.1 Julia
- 1.4.2 OpenGL
- 1.5 Similar Work
- 1.5.1 Other Languages
- 1.5.2 Ipython Notebook
- 1.5.3 Matlab
- 1.5.4 Mathematica
- 1.5.5 Other Graphic acceleration APIs

Kapitel 2 Background

# 2 Background

Kapitel 3 Architecture

#### 3 Architecture

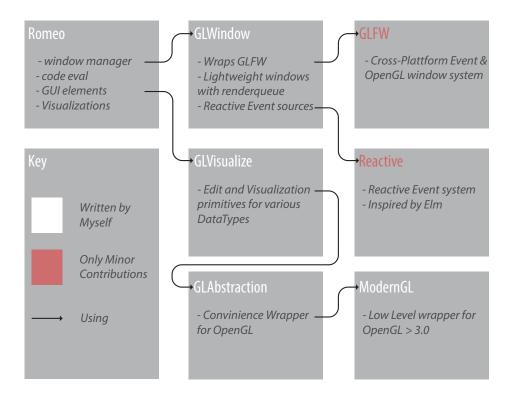

Figure 3: Main modules used in Romeo and their relation (simplified) This chapter is about the architecture of Romeo. Romeo itself just defines the high-level functionality of the editor. This includes window layout and connecting all the different event sources to create the wanted behavior. To do this, Romeo relies on a multitude of packages, which step for step abstract away the underlying low-level code that is used to do the window creation and rendering. GLVisualize is the main package, offering the rendering functionality and the editor widgets, like text fields and sliders. For rendering, GLVisualize relies on GLAbstraction, which defines a nice high-level interface to OpenGL. OpenGL function loading is done by ModernGL, which keeps all the function and Enums definitions from OpenGL with version higher than 3.0. The event management is handled by Reactive, which is a reactive event system written in Julia.

## 3.1 Event System

Holding everything together, since 1890.

#### 3.2 Low Level

#### 3.2.1 ModernGL

OpenGL is implemented by the video card vendor and is shipped via the video driver, which comes in the form of a C-Library. The challenge is, to load the function pointer system and vendor independently. Also one further complication is, that depending on the platform, function pointer are only available after an OpenGL context was created and may only be valid for this context. [?] This problem is solved, by initializing a function pointer cache with null and as soon as the function is called the first time the real pointer gets loaded. This is suboptimal, as the pointer cannot be inlined and has to be checked for null. In the newest version of Julia, this can be implemented even more efficiently with staged functions. Staged functions can be thought of as a runtime macro. At the first call of the function, code can be generated, which then will get compiled in time and replaces the function definition. This makes the an OpenGL function call nearly twice as fast. Like this, even C can be outperformed in terms of speed, as C doesn't have just in time compilation capabilities, so the function pointers can not be inlined like this.
